1 About this guide

This guide is intended for domain administrators and project members and explains how to manage project users and compute resources using the self-service panel.
2 Logging in to the self-service panel

To log in to the self-service panel, do the following:

1. Visit the panel's IP address on port 8800.
2. Enter your domain name (case sensitive) as well as user name and password. Alternatively, if you are given the link to the self-service panel for a specific domain, you will only need to provide the user name and password.
3 Managing users and projects

A user can be assigned one of the following roles:

- A domain administrator can manage virtual objects in all projects within the assigned domain as well as project and user assignment in the self-service panel.
- A project member acts as a project administrator in a specific domain in the self-service panel. A project member can be assigned to different projects and can manage virtual objects in them.

You can create, view, and edit users on the All users tab. Creating a user account differs slightly depending on the user role and is described in the following sections.

To edit the user credentials or permissions, click the ellipsis button next to the user and then click Edit.

Enabling and disabling a user account means allowing and prohibiting user login, respectively.

To enable/disable or remove a user, click the corresponding ellipsis button and select the desired action.

3.1 Creating users

To create a user, do as follows:

1. Select the domain in the drop-down list in the top right corner.
2. Switch to All users and click Create user.
3. In the Create user window, specify the user name, password, and, if required, a user email address and description. The user name must be unique within a domain.
4. Select the desired role from the Role drop-down menu.
5. Click Create.
3.2 Assigning users to projects

Domain administrators can manage project members’ assignment on the All projects and All users screens.

To assign a user to a project, do one of the following:

- On the All projects screen:
  1. Click the project to which you want to assign users (not the project name).
  2. On the project panel, click Assign members.
  3. In the Assign members window, choose one or multiple users to assign to the project. Only user accounts with the Project member role are displayed. Optionally, click Create project member to create a new project member in a new window.
  4. Click Assign.
On the All users screen:
1. Click the user account with the Project member role whom you want to assign to the project.
2. On the user panel, click Assign to project.
3. On the Assign user to projects window, select one or multiple projects, and then click Assign.

To unassign a user from a project, do one of the following:

On the All projects screen:
1. Click the project to unassign users from.
2. On the project panel, open the Members tab.
3. Click the cross icon next to a user you want to unassign.
On the All users tab:
1. Click the user to unassign from the project.
2. On the user panel, open the Projects tab.
3. Click the cross icon next to the project from which you want to unassign the user.

3.3 Viewing project quotas

Each project is allocated a certain amount of compute resources by means of quotas. To view quotas of a project, open Projects, click the desired project in the list, and then switch to the Quotas tab.
<table>
<thead>

4 Managing compute resources

4.1 Managing virtual machines

Each virtual machine (VM) is an independent system with an independent set of virtual hardware. Its main features are the following:

- A virtual machine resembles and works like a regular computer. It has its own virtual hardware. Software applications can run in virtual machines without any modifications or adjustment.
- Virtual machine configuration can be changed easily, for example, by adding new virtual disks or memory.
- Although virtual machines share physical hardware resources, they are fully isolated from each other (file system, processes, sysctl variables) and the compute node.
- A virtual machine can run any supported guest operating system.

The following table lists the current virtual machine configuration limits:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAM</td>
<td>1 TiB</td>
</tr>
<tr>
<td>CPU</td>
<td>48 virtual CPUs</td>
</tr>
<tr>
<td>Storage</td>
<td>15 volumes, 512 TiB each</td>
</tr>
<tr>
<td>Network</td>
<td>15 NICs</td>
</tr>
</tbody>
</table>

4.1.1 Supported guest operating systems

The guest operating systems listed below have been tested and are supported in virtual machines.

**Note**
Only the x64 architecture is supported.

Windows versions

- Windows Server 2019 - Essentials, Standard, Datacenter editions
- Windows Server 2016 - Essentials, Standard, Datacenter editions
- Windows Server 2012 R2 - Essentials, Standard, Datacenter editions
- Windows Server 2012 - Standard, Datacenter editions
- Windows Server 2008/2008 R2 - Standard, Datacenter editions
- Windows 10 - Home, Professional, Enterprise, Enterprise 2016 LTSB editions
- Windows 8.1 - Home, Professional, Enterprise editions
- Windows 7 - Home, Professional, Enterprise editions
Linux distributions and versions

- CentOS 8.x, 7.x, 6.x
- Red Hat Enterprise Linux 8.x, 7.x
- Debian 10.x, 9.x
- Ubuntu 20.04.x, 18.04.x, 16.04.x

4.1.2 Creating virtual machines

Before you proceed to creating VMs, check that you have these:

- Prepare a guest OS source (refer to "Managing images" (p. 31)):
  - A distribution ISO image of a guest OS to install in the VM
  - A template that is a boot volume in the QCOW2 format
  - A boot volume. You can obtain a boot volume after deleting a VM with the installed operating system. The boot volume will not be removed along with the VM only if during the creation it had the parameter **Delete on termination** set to **No**.
- Create one or more compute networks (refer to "Managing virtual networks" (p. 44)).
- Add an SSH key (refer to "Managing SSH keys" (p. 57)). You can specify an SSH key only when creating VMs from a template or boot volume.

To create a virtual machine, do the following:

1. On the **Virtual machines** screen, click **Create virtual machine**. A window will open where you will need to specify the VM parameters.
2. Specify a name for the new VM.
3. Select the VM boot media:
   - If you have an ISO image or a template
     a. Select **Image** in the **Deploy from** section, and then click **Specify** in the **Image** section.
     b. In the **Images** window, select the ISO image or template, and then click **Done**.
   - If you have a compute boot volume
     a. Select **Volume** in the **Deploy from** section, and then click **Specify** in the **Volumes** section.
     b. In the **Volumes** window, click **Attach**.
     c. In the **Attach volume** window, find and select the volume, and then click **Attach**.
If you attach more than one volume, the first attached volume becomes the boot volume, by default. To select another volume as bootable, place it first in the list by clicking the up arrow button next to it.

After selecting the boot media, volumes required for this media to boot will be automatically added to the Volumes section.

4. Configure the VM disks:
   a. In the Volumes window, make sure the default boot volume is large enough to accommodate the guest OS. Otherwise, click the ellipsis icon next to it, and then Edit. Change the volume size and click Save.
   b. (Optional) Add more disks to the VM by creating or attaching volumes. To do this, click the pencil icon in the Volumes section, and then Add or Attach in the Volumes window.
   c. Select volumes that will be removed during the VM deletion. To do this, click the pencil icon in the Volumes section, click the ellipsis icon next to the needed volume, and then Edit. Enable Delete on termination and click Save.
   d. When you finish configuring the VM disks, click Done.

5. (Optional) If you have any placements, the Placement drop-down list is displayed. Placements are created by the administrator to group nodes or VMs sharing a distinctive feature, like a special license. Select the placement corresponding to the VM characteristics. For more information, refer to "Manage placements" in the Administrator Guide.

6. Choose the amount of RAM and CPU resources that will be allocated to the VM in the Flavor section. In the Flavor window, select a flavor, and then click Done.

---

**Important**
When choosing a flavor for a VM, ensure it satisfies the hardware requirements of the guest OS.
7. Add network interfaces to the VM in the Networks section:
   a. In the Networks interfaces window, click Add, select a compute network, and then click Add.

   A network interface connected to the selected network will appear in the Network interfaces list.

   b. (Optional) Edit additional parameters of newly added network interfaces, such as IP and MAC addresses. To do this, click the ellipsis icon, click Edit, and then set the parameters. You will not be able to edit these parameters later. Instead, you will be able to delete the old network interface and replace it with a new one.

   c. When you finish configuring the VM network interfaces, click Done.

8. (Optional) If you have chosen to boot from a template or volume, which has cloud-init and OpenSSH installed:

   **Important**
   As cloud images have no default password, you can access VMs deployed from them only by using the key authentication method with SSH.
- Add an SSH key to the VM, to be able to access it via SSH without a password. In the **Select an SSH key** window, select an SSH key and then click **Done**.

- Add user data to customize the VM after launch, for example, change a user password. Write a cloud-config or shell script in the **Customization script** field or browse a file on your local server to load the script from.
To inject a script in a Windows VM, refer to the Cloudbase-Init documentation. For example, you can set a new password for the account using the following script:

```bash
# ps1
net user <username> <new_password>
```

9. After configuring all of the VM parameters, click **Deploy** to create and boot the VM.

If you are deploying the VM from an ISO image, you need to install the guest OS inside the VM by using the built-in VNC console. Virtual machines created from a template or a boot volume already have a pre-installed guest OS.

### 4.1.3 Connecting to virtual machines

To connect to a VM via the built-in VNC console, click **Console** on the VM right pane. The console will open in a separate browser window. In the console, you can send a key combination to a VM, take a screenshot of the console window, and download the console log (refer to "Troubleshooting virtual machines" (p. 21)).
To be able to connect to a VM via SSH, make sure it has cloud-init and OpenSSH installed (refer to "Preparing templates" (p. 33)). To connect to a VM via SSH, specify the username and VM IP address in the SSH terminal:

```bash
# ssh <username>@<VM_IP_address>
```

Linux cloud images have the default login, depending on the operating system, for example, `centos` or `ubuntu`. To connect to a Windows VM, enter the username that you specified during Cloudbase-Init installation.

If you have deployed a VM without specifying an SSH key, you also need to enter a password to log in to the VM.

### 4.1.4 Managing virtual machine power state

After you create a virtual machine, you can manage its power state by using available actions.

To see the full list of actions available for the VM current state, click the VM or the ellipsis button next to it. You can do the following:

- To power up a VM, click **Run**.
- To gracefully shut down a running VM, click **Shut down**. The default shutdown timeout, after which a virtual machine will be powered off, is 10 minutes. You can configure this timeout per VM by using the `vinfra service compute server stop --wait-time` command (refer to "vinfra service compute server stop" in the Administrator Command Line Guide).
- To forcibly cut off power from a VM, click **Power off**.
- To softly reboot a running VM, click **Reboot**.
- To reboot a VM without the guest OS graceful shutdown, click **Hard reboot**.
- To save the current VM state to a file, click **Suspend**. This may prove useful, for example, if you need to restart the host but do not want to quit the applications currently running in the VM or restart its guest OS.
- To restore a VM from the suspended state, click **Resume**.

### 4.1.5 Reconfiguring and monitoring virtual machines

To monitor virtual machine's CPU, storage, and network usage, select the VM and open the **Monitoring** tab.

The default time interval for the charts is twelve hours. To zoom into a particular time interval, select the internal with the mouse; to reset zoom, double-click any chart.

The following performance charts are available:

**CPU / RAM**

- CPU and RAM usage by the VM.

**Network**

- Incoming and outgoing network traffic.
Storage read/write

Amount of data read and written by the VM.

Read/write latency

Read and write latency. Hovering the mouse cursor over a point on the chart, you can also see the average and maximum latency for that moment, as well as the 95 and 99 percentiles.

Note

Averaged values are calculated every five minutes.

To reconfigure a VM, select it and, on the Overview tab, click the pencil icon next to a parameter you need to change. You cannot do the following:

- Change, detach, or delete the boot volume
- Manage non-boot volumes, except attaching and detaching
- Modify previously added network interfaces
- Attach and detach network interfaces to and from shelved VMs
- Change the flavor for running and shelved VMs

4.1.6 Shelving virtual machines

You can unbind a stopped VM from the node it is hosted on and release its reserved resources such as CPU and RAM. A shelved VM remains bootable and retains its configuration, including the IP addresses.

To shelve a stopped VM, click Shelve on the VM right pane. Virtual machines in other states can be shelved by clicking Shut down or Power off, and then selecting the check box Shelve virtual machine in the confirmation window.

To spawn a shelved VM on a node with enough resources to host it, click Unshelve on the VM right pane.

4.1.7 Rescuing virtual machines

Note

This feature is available via GUI only for Linux virtual machines. It is also available via the command line for Windows VMs.

If a VM experiences boot problems, you can send it to the rescue mode to access its boot volume. When a VM in the “Active” state is sent to the rescue mode, it is shut down softly first. Once the VM is in the rescue mode, you can connect to it via SSH or via the console. Its previous boot disk is now attached as a secondary one. You can mount the disk and repair it.

Before sending a VM to the rescue mode, consider the following:

- The rescue mode can only use qcow2 images (templates) for booting a VM. For instructions on making templates, refer to "Preparing templates" (p. 33).
You can send a VM to the rescue mode only if its current status is “Active” or “Shut down”.

There are only three actions available for the VM in the rescue mode: **Console**, **Exit rescue mode**, and **Delete**.

If a rescue image has cloud-init installed, then the VM booted from it can be accessed with the same SSH key that was used for its creation.

To put a VM to the rescue mode, follow the steps:

1. On the **Virtual machines** screen, click the required VM on the list.
2. On the VM right pane, click the ellipsis button on the toolbar. Then, click **Enter rescue mode**.
3. In the **Enter rescue mode** window, select an image to rescue the VM with. By default, the initial image used for creating the VM is selected. Click **Enter**.

The machine status changes to “Rescue”.

To return the VM to normal operation from the rescue mode, follow these steps:

1. On the **Virtual machines** screen, click the required VM on the list.
2. On the VM right pane, click **Exit rescue mode**.
3. In the **Exit rescue mode** window, click **Exit**. The VM will be automatically rebooted.

The VM status changes to “Active” and it boots from the original root disk.

**Note**

If the VM status changes to “Error” when exiting the rescue mode, you can reset its status with the **Reset state** action. The VM should then return to the “Rescue” status again.

### 4.1.8 Managing guest tools

This section explains how to install and uninstall the guest tools. This functionality is required for creating consistent snapshots of a running VM’s disks (refer to “Managing volume snapshots” (p. 42)).
Installing guest tools

To install the guest tools inside a virtual machine, do the following:

- Inside a Windows VM:
  1. Download the Windows guest tools ISO image provided by your system administrator.
  2. Mount the image inside the VM.
     - On Windows 8 or Windows Server 2012 or newer, you can natively mount an ISO image. To do this, right-click the guest tools ISO image and select **Mount**.
  3. Go to the mounted optical drive in Explorer and install the guest tools by running **setup.exe**.
  4. After the installation is complete, restart the VM.

- Inside a Linux VM:
  1. Download the Linux guest tools ISO image provided by your system administrator.
  2. Create a mount point for the optical drive with the guest tools image and run the installer:

```bash
# mkdir /mnt/cdrom
# mount <path_to_guest_tools_iso> /mnt/cdrom
# bash /mnt/cdrom/install
```

**Note**

Guest tools rely on the QEMU guest agent that is installed alongside the tools. The agent service must be running for the tools to work.

Uninstalling guest tools

If you find out that the guest tools are incompatible with some software inside a virtual machine, you can uninstall them by doing the following:

- Inside a Windows VM:
  1. Remove the QEMU device drivers from the device manager.

    **Important**
    
    Do not remove the VirtIO/SCSI hard disk driver and NetKVM network driver. Without the former, the VM will not boot; without the latter, the VM will lose network connectivity.

  2. Uninstall the QEMU guest agent and guest tools from the list of installed applications.

  3. Stop and delete **Guest Tools Monitor**:

    ```
    > sc stop VzGuestToolsMonitor
    > sc delete VzGuestToolsMonitor
    ```

  4. Unregister **Guest Tools Monitor** from **Event Log**.
5. Delete the autorun registry key for **RebootNotifier**:

   ```
   > reg delete HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Run /v \n   \VzRebootNotifier
   ```

6. Delete the `C:\Program Files\Qemu-ga\` directory.
   
   If **VzGuestToolsMonitor.exe** is locked, close all the Event Viewer windows. If it remains locked, restart the `eventlog` service:

   ```
   > sc stop eventlog
   > sc start eventlog
   ```

   After removing the guest tools, restart the virtual machine.

   - **Inside a Linux VM:**
     1. Remove the packages:
        a. On RPM-based systems (CentOS and other):

           ```
           # yum remove dkms-vzvirtio_balloon prl_nettool qemu-guest-agent-vz \n           vz-guest-udev
           ```

        b. On DEB-based systems (Debian and Ubuntu):

           ```
           # apt-get remove vzvirtio-balloon-dkms prl-nettool qemu-guest-agent-vz \n           vz-guest-udev
           ```

       If any of the packages listed above are not installed on your system, the command will fail. In this case, exclude these packages from the command and run it again.

     2. Remove the files:

        ```
        # rm -f /usr/bin/prl_backup /usr/share/qemu-ga/VERSION \n        /usr/bin/install-tools \n        /etc/udev/rules.d/90-guest_iso.rules /usr/local/bin/fstrim-static \n        /etc/cron.weekly/fstrim
        ```

     3. Reload the udev rules:

        ```
        # udevadm control --reload
        ```

     After removing guest tools, restart the virtual machine.

### 4.1.9 Troubleshooting virtual machines

If a VM fails to deploy, you can view the error message on the VM right pane. One of the possible root causes is that compute nodes lack free RAM or CPU resources to host the VM.
If a VM is stuck in a failed or transitional state, you can reset the VM to its last stable state: active, shut down or shelved. To do this, click **Reset state** on the VM right pane.

To troubleshoot a VM, you can also examine the VM console log by clicking **Download console log** on the VM right pane. The log will contain log messages only if logging is enabled inside the VM, otherwise the log will be empty.

To enable logging, do the following:

- In Linux VMs, enable the TTY1 and TTYS0 logging levels:
  1. Add the line `GRUB_CMDLINE_LINUX_DEFAULT=\"console=tty1 console=ttyS0\"` to the file `/etc/default/grub`.
  2. Depending on the boot loader, run either

     ```bash
     # grub-mkconfig -o /boot/grub/grub.cfg
     ```

     or

     ```bash
     # grub2-mkconfig -o /boot/grub2/grub.cfg
     ```

  3. Reboot the VM.

- In Windows VMs, enable Emergency Management Services (EMS) console redirection:
  1. Start **Windows PowerShell** by using administrator privileges.
  2. In the PowerShell console, set the COM port and baud rate for EMS console redirection. As Windows VMs have only the COM1 port with the transmission rate of 9600 bps, run:

     ```cmd
     bcdedit /emssettings EMSPORT:1
     ```

  3. Enable EMS for the current boot entry:

     ```cmd
     bcdedit /ems on
     ```

You may also enable driver status logging to see the list of loaded drivers. This can be useful for troubleshooting a faulty driver or long boot process. Do the following:

1. Start **System Configuration** by using administrator privileges.

2. In the **System Configuration** windows, open the **Boot** tab, and select the check boxes **OS boot information** and **Make all boot settings permanent**.

3. Confirm the changes and restart the system.

### 4.1.10 Deleting virtual machines

To remove a virtual machine, click its ellipse button, and then click **Delete**. To remove multiple VMs at once, select them, and then click **Delete**.

A VM is removed along with its disks that have the **Delete on termination** option enabled during the VM deployment.
4.2 Managing Kubernetes clusters

Self-service users can deploy ready-to-use Kubernetes clusters with persistent storage for managing containerized applications.

A Kubernetes cluster includes the following components:

<table>
<thead>
<tr>
<th>Component</th>
<th>Name and version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Underlying OS</td>
<td>Fedora 29 Atomic Host</td>
</tr>
<tr>
<td>Container runtime</td>
<td>Docker 1.13.1</td>
</tr>
<tr>
<td>Network plugin</td>
<td>Flannel with VXLAN</td>
</tr>
</tbody>
</table>

The prerequisites for creating a Kubernetes cluster are:

- The Kubernetes-as-a-service component. It can be deployed along with the compute cluster or later (refer to the Administrator Guide).
- A network that will interconnect the Kubernetes master and worker nodes. It can be either a shared physical network or a virtual network linked to a physical one via a virtual router. The virtual network needs to have a gateway and a DNS server specified.
- An SSH key that will be installed on both the master and worker nodes.
- Enough resources for all of the Kubernetes nodes, taking their flavors into account.

**Important**
It is also required that the network where you create a Kubernetes cluster does not overlap with these default networks:

- 10.100.0.0/24—Used for pod-level networking
- 10.254.0.0/16—Used for allocating Kubernetes cluster IP addresses

To create a Kubernetes cluster, on the **Kubernetes clusters** screen, click **Create** on the right. A window will open where you can set your cluster parameters:

1. In the **Cluster** section, select a Kubernetes version, enter a cluster name, and select an SSH key.

```markdown
<table>
<thead>
<tr>
<th>Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes version</td>
</tr>
<tr>
<td>SSH key</td>
</tr>
</tbody>
</table>
```
2. In the **Network** section, select a virtual router mentioned in the prerequisites above. It is also recommended to check the **Use a floating IP address** box. In this case, the Kubernetes nodes will be assigned public IP addresses, simplifying access to them.

3. In the **Master node** section, select a flavor, and then choose whether or not to enable high availability for the master node. If you enable high availability, three master node instances will be created. They will work in the Active/Active mode.

4. In the **Container volume** section, select a storage policy, and then enter size for volumes on both master and worker nodes.

5. In the **Workers** section, set a number of workers to create, and then select a flavor for each worker.
6. Finally, click Create.

Creation of the Kubernetes cluster will start. The master and worker nodes will appear on the Virtual machines screen, while their volumes will show up on the Volumes screen.

After the cluster is ready, click Kubernetes access for instructions on how you can access the dashboard.

To delete a Kubernetes cluster, click it on the Kubernetes clusters screen and click Delete. The master and worker VMs will be deleted along with their volumes.

4.2.1 Using persistent volumes for Kubernetes pods

Kubernetes allows using compute volumes as persistent storage for pods. Persistent volumes (PV) exist independently of pods, meaning that such a volume persists after the pod it is mounted to is deleted. This PV can be mounted to other pods for accessing data stored on it. You can provision PVs dynamically, without having to create them manually, or statically, using volumes that exist in the compute cluster.

Creating storage classes

In Virtuozzo Hybrid Infrastructure, storage classes map to compute storage policies defined in the admin panel. Creating a storage class is required for all storage operations in a Kubernetes cluster.

To create a storage class, click + Create on the Kubernetes dashboard and specify a YAML file that defines this object. For example:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: msc
provisioner: csi-cinderplugin
parameters:
  type: default
```

This manifest describes the storage class msc with the storage policy default. The storage policy must exist in the compute cluster and be specified in the storage quotas to the current project.

Dynamically provisioning persistent volumes

Persistent volumes can be dynamically provisioned via persistent volume claims (PVC). A PVC requests for a PV of a specific storage class, access mode, and size. If a suitable PV exists in the cluster, it is bound to the claim. If suitable PVs do not exist but can be provisioned, a new volume is created and bound to the claim. Kubernetes uses a PVC to obtain the PV backing it and mounts it to the pod.

**Important**

A pod and the persistent volume claim it uses must exist in the same namespace.

You can dynamically provision a PV to a pod as follows:
1. Access the Kubernetes cluster via the dashboard. Click **Kubernetes access** for instructions.

2. On the Kubernetes dashboard, create a storage class, as described in "Creating storage classes" (p. 25).

3. Create a persistent volume claim. To do it, click + **Create** and specify the following YAML file:

   ```yaml
   apiVersion: v1
   kind: PersistentVolumeClaim
   metadata:
     name: mypvc
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 10Gi
     storageClassName: mysc
   ```

   This manifest specifies the persistent volume claim `mypvc` that requests from the storage class `mysc` a volume of at least 10 GiB that can be mounted in the read/write mode by a single node. Creation of the PVC triggers dynamic provisioning of a persistent volume that satisfies the claim's requirements. Kubernetes then binds it to the claim.

4. Create a pod and specify the PVC as its volume. To do it, click + **Create** and enter the following YAML file:

   ```yaml
   apiVersion: v1
   kind: Pod
   ```
This configuration file describes the pod nginx that uses the persistent volume claim mypvc. The persistent volume bound to the claim will be accessible at /var/lib/www/html inside the nginx container.

**Statically provisioning persistent volumes**

You can mount existing compute volumes to pods using static provisioning of persistent volumes. To mount a compute volume, do the following:

1. In the self-service panel, obtain the ID of the desired volume.

2. Access the Kubernetes cluster via the dashboard. Click **Kubernetes access** for instructions.
3. On the Kubernetes dashboard, create a storage class, as described in "Creating storage classes" (p. 25).

4. Create a persistent volume. To do it, click + Create and specify the following YAML file:

```yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  annotations:
    pv.kubernetes.io/provisioned-by: csi-cinderplugin
  name: mypv
spec:
  accessModes:
  - ReadWriteOnce
  capacity:
      storage: 10Gi
  csi:
    driver: cinder.csi.openstack.org
    fsType: ext4
    volumeHandle: c5850e42-4f9d-42b5-9bee-8809dedae424
  persistentVolumeReclaimPolicy: Delete
  storageClassName: mysc
```

This manifest specifies the persistent volume mypv from the storage class mysc that has 10 GiB of storage and access mode that allows it to be mounted in the read/write mode by a single node. The PV mypv uses the compute volume with the ID c5850e42-4f9d-42b5-9bee-8809dedae424 as backing storage.

5. Create a persistent volume claim. Before you define the PVC, make sure the PV is created and has the status “Available”. The existing PV must meet the claim's requirements to storage size, access mode and storage class. Click + Create and specify the following YAML file:

```yaml
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mypvc
spec:
  accessModes:
  - ReadWriteOnce
  resources:
    requests:
      storage: 10Gi
  storageClassName: mysc
```

Once the persistent volume claim mypvc is created, the volume mypv is bound to it.
6. Create a pod and specify the PVC as its volume. Use the example from Step 3 in "Dynamically provisioning persistent volumes" (p. 25).

In the self-service panel, the compute volume will be mounted to the virtual machine running the Kubernetes pod.

```
myvolume
```

Details

- **Name**: mypvc
- **Namespace**: default
- **Annotations**: pv.kubernetes.io/bind-completed: yes
  pv.kubernetes.io/bound-by-controller: yes
- **Creation Time**: 2020-02-04T14:53 UTC
- **Status**: Bound
- **Volume**: mypv
- **Access modes**: ReadWriteOnce
- **Storage class**: mysc

```

4.2.2 Creating external load balancers in Kubernetes

In Kubernetes, you can create a service with an external load balancer that provides access to it from public networks. The load balancer will receive a publicly accessible IP address and route incoming requests to the correct port on the Kubernetes cluster nodes.

To create a service with an external load balancer, do the following:

1. Access the Kubernetes cluster via the dashboard. Click Kubernetes access for instructions.
2. On the Kubernetes dashboard, create a deployment and service of the LoadBalancer type. To do it, click + Create and specify a YAML file that defines these objects. For example:
   - If you have deployed the Kubernetes cluster in a shared physical network, specify the following manifest:

   ```yaml
   apiVersion: apps/v1beta1
   kind: Deployment
   metadata:
     name: nginx
   spec:
     replicas: 2
   template:
     metadata:
       labels:
         app: nginx
       spec:
         containers:
           - name: nginx
             image: nginx
             ports:
               - containerPort: 80
   ---
   
   kind: Service
   apiVersion: v1
   metadata:
     name: load-balancer
   annotations:
     service.beta.kubernetes.io/openstack-internal-load-balancer: "true"
   spec:
     selector:
       app: nginx
     type: LoadBalancer
     ports:
       - port: 80
         targetPort: 80
         protocol: TCP
   
   The manifest above describes the deployment nginx with a replica set of two pods and the service load-balancer with the LoadBalancer type. The annotation used for the service indicates that the load balancer will be internal.
Once the load balancer is created, it will be allocated an IP address from the shared physical network and can be accessed at this external endpoint.

- If you have deployed the Kubernetes cluster in a virtual network linked to a physical one via a virtual router, you can use the YAML file above without the annotations section for the load-balancer service. The created load balancer will receive a floating IP address from the physical network and can be accessed at this external endpoint.

The load balancer will also appear in the self-service panel, where you can monitor its performance and health. For example:

### 4.3 Managing images

Virtuozzo Hybrid Infrastructure allows you to upload ISO images and templates that can be used to create VM volumes. An ISO image is a typical OS distribution that needs to be installed on disk. In turn, a template is a ready volume in the QCOW2 format with an installed operating system and applications and a set minimum size. Many OS vendors offer templates of their operating systems under the name "cloud images". For a list of guest OSes that are supported in virtual machines, refer to "Supported guest operating systems" (p. 11).

#### 4.3.1 Uploading and removing images

To add an image, do the following:

1. On the **Images** screen, click **Add image**.
2. In the **Add image** window, do the following:
   a. Click **Browse** and select a template or ISO file.
   b. Specify an image name to be shown in the admin panel.
   c. Select the correct OS type from the drop-down list.
3. Click **Add** to start uploading the image. Upload progress will be shown in the bottom right corner.

**Important**
The OS type affects VM parameters such as hypervisor settings. VMs created from an image with an incorrect OS type may not work correctly, for example, they may crash.

To download or remove an image, click the ellipsis button next to it and click the desired action.

### 4.3.2 Creating volumes from images

You can create volumes from both ISO images and templates. Do the following:

1. Go to the **Images** screen, and then click the required image.
2. On the image panel, click **Create volume**.
3. In the **Create volume** window, specify the volume name, size, and select a storage policy.
4. Click **Create**.

The new volume will appear on the **Volumes** screen.

### 4.3.3 Mounting ISO images to virtual machines

**Note**

This feature is supported only for Linux virtual machines.

To mount an ISO image to a Linux VM, do the following:

1. Create a volume from the ISO image, as described in "Creating volumes from images" (p. 32).
2. Attach the resulting volume to the desired VM, as described in "Attaching and detaching volumes" (p. 40).

The mounted disk will appear inside the Linux VM.

### 4.3.4 Preparing templates

You may need to create a template in these cases:

- To rescue a virtual machine
- To create a VM accessible via SSH
To create a VM customizable with user data

You can create a template from an existing boot volume and deploy multiple VMs from this template. Make sure to install cloud-init in the boot volume before creating the image (refer to the sections below).

Do the following:

1. Power off the VM that the original volume is attached to.
2. Switch to the Volumes screen, click volume’s ellipsis button and select Create image.
3. In the Create image window, enter an image name, and then click Create.

The new image will appear on the Images screen.

Preparing Linux templates

As all Linux guests have OpenSSH Server pre-installed by default, you only need to make sure a Linux template has cloud-init installed.

The easiest way to get a Linux template with cloud-init installed is to obtain it from its official repository.

Preparing Windows templates

Windows guests have neither Cloudbase-Init nor OpenSSH Server pre-installed by default. You need to install and configure them manually.

Do the following:

1. Log in to a Windows VM.
2. Create a new administrator account that will be used for SSH connections and log in with it.
3. To install and configure OpenSSH Server:
a. Run Windows PowerShell with administrator privileges and set the execution policy to unrestricted to be able to run scripts:

```
> Set-ExecutionPolicy Unrestricted
```

b. Download OpenSSH Server (for example, from the GitHub repository), extract the archive into the C:\Program Files directory, and then install it by running:

```
> & 'C:\Program Files\OpenSSH-Win64\install-sshd.ps1'
```

c. Start the sshd service and set its startup type to “Automatic”:

```
> net start sshd
> Set-Service sshd -StartupType Automatic
```

d. Open TCP port 22 for the OpenSSH service in the Windows Firewall:

- On Windows 8.1, Windows Server 2012, and newer versions, run

```
> New-NetFirewallRule -Protocol TCP -LocalPort 22 -Direction Inbound -Action Allow -DisplayName OpenSSH
```

```
> netsh advfirewall firewall add rule name=sshd dir=in action=allow protocol=TCP localport=22
```

e. Open the C:\ProgramData\ssh\sshd_config file:

```
> notepad 'C:\ProgramData\ssh\sshd_config'
```

Comment out the following lines at the end of the file:

```
#Match Group administrators
#AuthorizedKeysFile __PROGRAMDATA__/ssh/administratorsAuthorizedKeys
```

Save the changes.

f. Create the .ssh directory in C:\Users\<current_user> and an empty authorized_keys file inside it:

```
> cd C:\Users\<current_user>
> mkdir .ssh
> notepad .\.ssh\authorized_keys
```

Remove the .txt extension from the created file:

```
> move .\.ssh\authorized_keys.txt .\.ssh\authorized_keys
```

g. Modify the permissions for the created file to disable inheritance:
> icacls \.ssh\authorized_keys /inheritance:r

4. Download Cloudbase-Init (for example, from the official site), launch the installation, and then follow the on-screen instructions:
   a. In the **Configuration options** window, enter the current username in the **Username** field:

   ![Configuration options window](image)

   **Important**
   The user account password will be reset on the next VM startup. You will be able to log in with this account by using the key authentication method or you can set a new password with a customization script.

   b. When the installation is complete, do not run Sysprep and click **Finish**.
c. Run Windows PowerShell with administrator privileges and open the file C:\Program Files\Cloudbase Solutions\Cloudbase-Init\conf\cloudbase-init.conf:

```
> notepad 'C:\Program Files\Cloudbase Solutions\Cloudbase-Init\conf\cloudbase-init.conf'
```

Add `metadata_services` and `plugins` on two lines:

```
metadata_services=
cloudbaseinit.metadata.services.configdrive.ConfigDriveService,
cloudbaseinit.metadata.services.httbservice.HttpService,
plugins=cloudbaseinit.plugins.common.mtu.MTUPlugin,
cloudbaseinit.plugins.windows.ntpcclient.NTPClientPlugin,
cloudbaseinit.plugins.common.sethostname.SetHostNamePlugin,
cloudbaseinit.plugins.windows.createuser.CreateUserPlugin,
cloudbaseinit.plugins.common.networkconfig.NetworkConfigPlugin,
cloudbaseinit.plugins.windows.licensing.WindowsLicensingPlugin,
cloudbaseinit.plugins.common.sshpublickeys.SetUserSSHPublicKeysPlugin,
cloudbaseinit.plugins.windows.extendvolumes.ExtendVolumesPlugin,
cloudbaseinit.plugins.common.setuserpassword.SetUserPasswordPlugin,
cloudbaseinit.plugins.common.userdata.UserDataPlugin,
cloudbaseinit.plugins.windows.winrmlistener.ConfigWinRMListenerPlugin,
cloudbaseinit.plugins.windows.winrmcertificateauth.ConfigWinRMCertificateAuthPlugin,
cloudbaseinit.plugins.common.localscripts.LocalScriptsPlugin
```
5. Stop the VM.
6. After the VM is shut down, convert its boot volume to a template (refer to "Creating images from volumes" (p. 41)).

4.4 Managing volumes

A volume in Virtuozzo Hybrid Infrastructure is a virtual disk drive that can be attached to a virtual machine. The integrity of data in volumes is protected by the redundancy mode specified in the storage policy.

Note
Additional virtual disks attached to VMs need to be initialized inside the guest OS by standard means before they can be used.

4.4.1 Creating, editing, and removing volumes

To create a volume, do the following:

1. On the Volumes screen, click Create volume.
2. In the Create volume window, specify a volume name and size in gigabytes, select a storage policy, and then click Create.

To edit a volume, select it and click the pencil icon next to a parameter you need to change. Note the following restrictions:

- You cannot shrink volumes.
- To extend volumes that are in use, stop the VM first.
- You cannot change the volume redundancy type.

To remove a volume, click its ellipsis button then click Delete. To remove multiple volumes at once, select them and click Delete. To remove a volume that is in use, detach it first.

Note
A volume is removed along with all of its snapshots.

4.4.2 Cloning volumes

You can clone volumes that are not attached to VMs or attached to stopped VMs. To clone a volume, do the following:

1. On the Volumes screen, click a volume.
2. In the volume right pane, click Clone.
3. In the **Clone volume** window, specify a volume name, size, and storage policy. Click **Clone**.

4.4.3 Attaching and detaching volumes

You can add a writable virtual disk drive to a VM by attaching a volume to the VM. To do this:

1. On the **Volumes** screen, click the ellipsis button next to an unused volume, and then click **Attach** in the context menu.
2. In the **Attach volume** window, select the VM from the drop-down list, and then click **Done**.

To detach a volume, do the following:

1. Click the ellipsis button next to the volume that is in use.
2. If the VM is not running, click **Detach**.
3. If the VM is running, you can only click **Force detach** to immediately detach the volume.

**Warning!**
There is a risk of data loss.

### 4.4.4 Creating images from volumes

To create multiple VMs with the same boot volume, you can create an image from an existing boot volume and deploy VMs from it. Make sure to install cloud-init in the volume before creating the image.

Do the following:

1. Power off the VM that the original volume is attached to.
2. Switch to the **Volumes** screen, click volume’s ellipsis button and select **Create image**.
3. In the Create image window, enter an image name, and then click Create.

The new image will appear on the Images screen.

4.4.5 Managing volume snapshots

You can save the current state of a VM file system or user data by creating a snapshot of a volume. A snapshot of a boot volume may be useful, for example, before updating VM software. If anything goes wrong, you will be able to revert the VM to a working state at any time. A snapshot of a data volume can be used for backing up user data and testing purposes.

To create a snapshot of a volume, do the following:

1. On the Volumes screen, click a volume.
2. In the volume right pane, switch to Snapshots, and then click Create snapshot.
Note
To create a consistent snapshot of a running VM's volume, make sure the guest tools are installed in the VM. The QEMU guest agent included in the guest tools image automatically quiesces the filesystem during snapshotting. For instructions on installing the guest tools, refer to "Installing guest tools" (p. 20).

Once the snapshot is created, you can see and manage it on the Snapshots tab on the volume right pane.

You can do the following:

- Create a new volume from the snapshot.
- Create a template from the snapshot.
- Discard all changes that have been made to the volume since the snapshot was taken. This action is available only for VMs with the "Shut down" and "Shelved offloaded" statuses.

**Warning!**
As each volume has only one snapshot branch, all snapshots created after the snapshot you are reverting to will be deleted. If you want to save a subsequent snapshot before reverting, create a volume or an image from it first.

- Change the snapshot name and description.
- Reset the snapshot stuck in an "Error" state or transitional state to the "Available" state.
- Remove the snapshot.

To perform these actions, click the ellipsis button next to a snapshot, and then click the corresponding action.
4.5 Managing virtual networks

To add a new virtual network, do the following:

1. On the Networks screen, click Create virtual network.

2. On the Network configuration step, do the following:
   a. Enable or disable IP address management:
      - With IP address management enabled, VMs connected to the network will automatically be assigned IP addresses from allocation pools by the built-in DHCP server and use custom DNS servers. Additionally, spoofing protection will be enabled for all VM network ports by default. Each VM network interface will be able to accept and send IP packets only if it has IP and MAC addresses assigned. You can disable spoofing protection manually for a VM interface, if required.
      - With IP address management disabled, VMs connected to the network will obtain IP addresses from the DHCP servers in that network, if any. Also, spoofing protection will be disabled for all VM network ports, and you cannot enable it manually. This means that each VM network interface, with or without assigned IP and MAC addresses, will be able to accept and send IP packets.

   In any case, you will be able to manually assign static IP addresses from inside the VMs.
   b. Specify a name, and then click Next.

3. If you enabled IP address management, you will move on to the Subnet configuration step, where you can configure the network settings for IP address management:
   a. Specify the network's IPv4 address range and, optionally, specify a gateway. If you leave the Gateway field blank, the gateway will be omitted from network settings.
   b. Enable or disable the built-in DHCP server:
      - With the DHCP server enabled, VM network interfaces will automatically be assigned IP addresses: either from allocation pools or, if there are no pools, from the network's entire IP range.
      - With the DHCP server disabled, VM network interfaces will still get IP addresses, but you will have to manually assign them inside VMs.

The virtual DHCP service will work only within the current network and will not be exposed to other networks.
c. Specify one or more allocation pools (ranges of IP addresses that will be automatically assigned to VMs).

d. Specify DNS servers that will be used by virtual machines. These servers can be delivered to VMs via the built-in DHCP server or by using the cloud-init network configuration (if cloud-init is installed in the VM).

e. Click **Next**.

4. On the **Summary** step, review the configuration, and then click **Create virtual network**.

To view and edit parameters of a virtual network, click it on the **Networks** screen. On the network right pane, you can edit the network name and IP management settings. To do this, click the pencil icon next to the required section, and then make changes.
To delete a compute network, click the ellipsis icon next to it, and then click Delete. To remove multiple compute networks at once, select them, and then click Delete. Before deleting a compute network, make sure no VMs are connected to it.

### 4.6 Managing virtual routers

Virtual routers provide L3 services such as routing and Source Network Address Translation (SNAT) between virtual and physical networks, or different virtual networks:

- A virtual router between virtual and physical networks provides access to public networks, such as the Internet, for VMs connected to this virtual network.
- A virtual router between different virtual networks provides network communication for VMs connected to these virtual networks.

A virtual router has two types of ports:

- An external gateway that is connected to a physical network.
- An internal port that is connected to a virtual network.

With virtual routers, you can do the following:

- Create virtual routers
- Change external or internal router interfaces
- Create, edit, and delete static routes
- Change a router name
- Delete a router

**Note**

A router can only connect networks that have IP management enabled.

To create a virtual router, do the following:

1. On the **Networks** screen, make sure the compute networks that are to be connected to a router have a gateway specified.
2. Navigate to the **Routers** screen, and then click **Add router**.
3. In the **Add router** window:
   a. Specify a router name.
   b. From the **Network** drop-down menu, select a physical network through which external access will be provided via an external gateway. The new external gateway will pick an unused IP address from the selected physical network.
   c. In the **Add internal interfaces** section, select one or more virtual networks to connect to a router via internal interfaces. The new internal interfaces will attempt to use the gateway IP address of the selected virtual networks by default.
   d. (Optional) Select or deselect the **SNAT** check box to enable or disable SNAT on the external gateway of the router. With SNAT enabled, the router replaces VM private IP addresses with the public IP address of its external gateway.
4. Click Create.

4.6.1 Managing router interfaces

To add an external router interface, do the following:

1. If you already have an external gateway, remove the existing one first.
2. On the Routers screen, click the router name to open the list of its interfaces.
3. Click Add on the toolbar, or click Add interface if there are no interfaces to show.
4. In the Add interface window, do the following:
a. Select **External gateway**.

b. From the **Network** drop-down menu, select a physical network to connect to the router. The new interface will pick an unused IP address from the selected physical network. You can also provide a specific IP address from the selected physical network to assign to the interface in the **IP address** field.

c. (Optional) Select or deselect the **SNAT** check box to enable or disable SNAT on the external gateway of the router. With SNAT enabled, the router replaces VM private IP addresses with the public IP address of its external gateway.

5. Click **Add**.

To edit the external gateway parameters, click the ellipsis icon next to it, and then **Edit**. In the **Edit interface** window, you can change the external gateway IP address and enable or disable SNAT on it. To save your changes, click **Save**.
To add an internal router interface, do the following:

1. On the **Routers** screen, click the router name to open the list of its interfaces.
2. Click **Add**.
3. In the **Add interface** window, select a network to connect to the router from the **Network** drop-down menu. The new interface will attempt to use the gateway IP address of the selected virtual network by default. If it is in use, specify an unused IP address from the selected virtual network to assign to the interface in the **IP address** field.

4. Click **Add**.

To remove a router interface, click the ellipsis icon next to it, and then click **Delete**.

### 4.6.2 Managing static routes

You can also configure static routes of a router by manually adding entries into its routing table. This can be useful, for example, if you do not need a mutual connection between two virtual networks and want only one virtual network to be accessible from the other.

Consider the following example:
The virtual machine **VM1** is connected to the virtual network **private1** (192.168.128.0/24) via the network interface with IP address 192.168.128.10.

The virtual machine **VM2** is connected to the virtual network **private2** (192.168.30.0/24) via the network interface with IP address 192.168.30.10.

The router **router1** connects the network **private1** to the physical network via the external gateway with the IP address 10.94.129.73.

The router **router2** connects the network **private2** to the physical network via the external gateway with the IP address 10.94.129.74.

To be able to access **VM2** from **VM1**, you need to add a static route for **router1**, specifying the CIDR of **private2**, that is 192.168.30.0/24, as the destination subnet and the external gateway IP address of **router2**, that is 10.94.129.74, as the next hop IP address. In this case, when an IP packet for 192.168.30.10 reaches **router1**, it will be forwarded to **router2** and then to **VM2**.

To create a static route for a router, do the following:

1. On the **Routers** screen, click the router name. Open the **Static routes** tab, and then click **Add** on the right pane. If there are no routes to show, click **Add static route**.

2. In the **Add static route** window, specify the destination subnet range and mask in CIDR notation and the next hop's IP address. The next hop's IP address must belong to one of the networks that the router is connected to.

3. Click **Add**.

---

Add static route

Specify static route parameters

Destination subnet and mask
192.168.30.0/24

Next hop
10.94.129.74

The next hop's IP address must belong to one of the networks that the router is connected to.

---

Copyright © 2016-2020 Virtuozzo International GmbH
To edit a static route, click the ellipsis icon next to it, and then click **Edit**. In the **Edit static route** window, change the desired parameters, and then click **Save**.

To remove a static route, click the ellipsis icon next to it, and then click **Delete**. To remove multiple routes at once, select them, and then click **Delete**.

### 4.7 Managing floating IP addresses

A virtual machine connected to a virtual network can be accessed from public networks, such as the Internet, by means of a floating IP address. Such an address is picked from a physical network and mapped to the VM's private IP address. The floating and private IP addresses are used at the same time on the VM's network interface. The private IP address is used to communicate with other VMs on the virtual network. The floating IP address is used to access the VM from public networks. The VM guest operating system is unaware of the assigned floating IP address.

Note the following prerequisites:

- A VM must have a fixed private IP address.
- A virtual router must connect the physical network, from which a floating IP will be picked, with the VM's virtual network.

To create a floating IP address and assign it to a VM, do the following:

1. On the **Floating IPs** screen, click **Add floating IP**.
2. In the **Add floating IP address**, select a physical network, from which a floating IP will be picked, and a VM network interface with a fixed private IP address.
3. Click **Add**.

A floating IP address can be re-assigned to another virtual machine. Do the following:

---

*Note: The image is not relevant to the text content.*
1. Click the ellipsis icon next to the floating IP address, and then click Unassign.
2. Once the VM name disappears in the Assigned to column, click the ellipsis icon again, and then select Assign.
3. In the Assign floating IP address window, select a VM network interface with a fixed private IP address.
4. Click Assign.

To remove a floating IP address, unassign it from a VM, as described above, then click the ellipsis icon again and select Delete.

4.8 Managing load balancers

Virtuozzo Hybrid Infrastructure offers load balancing as a service for the compute infrastructure. Load balancing ensures fault tolerance and improves performance of web applications by distributing incoming network traffic across virtual machines from a balancing pool. A load balancer receives and then routes incoming requests to a suitable VM based on a configured balancing algorithm and VM health.

Note the following requirements:

- A load balancer can only operate in networks with enabled IP management.
- All VMs in balancing pools must have fixed IP addresses.

You can create a load balancer with balancing pools as follows:

1. On the Load balancers screen, click Create load balancer.
2. In the Create load balancer window, do the following:
   a. Specify a name and optionally description.
   b. Enable or disable high availability:
      - With high availability enabled, two load balancer instances will be created. They will work in the Active/Standby mode according to the Virtual Router Redundancy Protocol (VRRP).
      - With high availability disabled, a single load balancer instance will be created.

   ```
   Name
   LBaa51

   Description (optional)
   Custom load balancer

   [ ] High availability
   ```

3. In the Network settings section, select the network that the load balancer will operate in and, optionally, specify an IP address that will be allocated to the load balancer.
4. If a chosen virtual network is connected to a physical network via a router, you can assign a floating IP address to the load balancer. To do it, select Use a floating IP address, and from the
drop-down menu that appears, choose either to use an available floating IP address or to create a new one.

5. In the **Balancing pools** section, create a balancing pool to forward traffic from the load balancer to virtual machines by clicking **Add**.
   
   In the **Create balancing pool** window that opens, do the following:
   
   a. In the **Forwarding rule** section, select a forwarding rule from the load balancer to the backend protocol: **HTTPS -> HTTPS, HTTPS -> HTTP, HTTP -> HTTP, or TCP -> TCP**. Additionally, specify the ports for incoming and destination connections in the **LB port** and **Backend port** fields.
   
   Note the following:
   
   - With the **HTTPS -> HTTPS** rule, all virtual machines need to have the same SSL certificate (or a certificate chain).
   - With the **HTTPS -> HTTP** rule, you need to upload an SSL certificate (or a certificate chain) in the PEM format and a private key in the PEM format.

   **Important**
   The forwarding rule cannot be changed after the load balancer is created.
   
   b. In the **Balancing settings** section, select the balancing algorithm:
   
   - **Least connections**. Requests will be forwarded to the VM with the least number of active connections.
   - **Round robin**. All VMs will receive requests in the round-robin manner.
   - **Source IP**. Requests from a unique source IP address will be directed to the same VM.
Enable/disable the **Sticky session** option to enable/disable session persistence. The load balancer will generate a cookie that will be inserted into each response. The cookie will be used to send future requests to the same VM.

**Note**  
This option is not available in the SSL passthrough mode.

---

In the **Members** section, add members, that is, virtual machines, to the balancing pool by clicking **Add**. Each VM can be included to multiple balancing pools.

In the **Add members** window that opens, select the desired VMs, and then click **Add**.

---

In the **Health monitor** section, select the protocol that will be used for monitoring members availability:

- **HTTP/HTTPS**. The HTTP/HTTPS method GET will be used to check for the response status code 200. Additionally, specify the URL path to the health monitor.
- **TCP**. The health monitor will check the TCP connection on the backend port.
- **PING**. The health monitor will check members' IP addresses.

**Important**  
The protocol cannot be changed after the load balancer is created.
By default, the health monitor removes a member from a balancing pool if it fails three consecutive health checks of five-second intervals. When a member returns to operation and responds successfully to three consecutive health checks, it is added to the pool again. You can manually set the health monitor parameters, such as the interval after which VM health is checked, the time after which the monitor times out, healthy and unhealthy thresholds. To change the default parameters, click **Edit parameters**, enter the desired values, and then click **Save**.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval</td>
<td>5</td>
<td>Interval after which member health is checked.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from 5 to 300 seconds</td>
</tr>
<tr>
<td>Timeout</td>
<td>5</td>
<td>The time a monitor has to poll a member. Must be less than the interval.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from 5 to 60 seconds</td>
</tr>
<tr>
<td>Healthy threshold</td>
<td>3</td>
<td>The number of consecutive successful checks after which a member is marked as healthy</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from 1 to 10 attempts</td>
</tr>
<tr>
<td>Unhealthy threshold</td>
<td>3</td>
<td>The number of consecutive unsuccessful checks after which a member is marked as unhealthy</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from 1 to 10 attempts</td>
</tr>
</tbody>
</table>

6. Click **Create**.

6. Add more balancing pools, as described above, if required.
7. Click **Create**.

Once the load balancer is created, you can monitor its performance and health on the **Overview** tab of its right pane.

The following charts are available:

**Members state**

The total number of members in the balancing pools grouped by status: “Healthy,” “Unhealthy,” “Error,” and “Disabled”.

**CPU/RAM**

CPU and RAM usage by the load balancer.

**Network**

Incoming and outgoing network traffic.

**Active connections**

The number of active connections.

**Error requests**

The number of error requests.

You can see the load balancer parameters on its **Properties** tab.

To edit the name or description of a load balancer, click the ellipsis icon next to it, and then click **Edit**.

To disable/enable or remove a load balancer, click the ellipsis icon next to it, and then click the desired action. To remove multiple load balancers at once, select them, and then click **Delete**.

---

4.8.1 Managing balancing pools

To see a list of balancing pools in a load balancer, click its name.
To add another balancing pool to a load balancer, click Create balancing pool, and then fill in the fields, as described in "Managing load balancers" (p. 52). The newly added pool will appear in the list of balancing pools.

You can open the pool right pane to monitor its performance and health on the Overview tab, see its parameters on the Properties tab, and manage its members on the Members tab.

To edit the balancing settings such as the balancing algorithm and session persistence, click the ellipsis icon next to a pool, and then click Edit. To edit the health monitor parameters, click the ellipsis icon next to a pool, and then click Edit health monitor.

To add more members to a balancing pool, click the ellipsis icon next to it, and then click + Add members.

To remove a balancing pool, click the ellipsis icon next to it, and then click Delete. To remove multiple balancing pools at once, select them, and then click Delete.

4.9 Managing SSH keys

Use of SSH keys allows you to secure SSH access to virtual machines. You can generate a key pair on a client from which you will connect to VMs via SSH. The private key will be stored on the client and you will be able to copy it to other nodes. The public key will need to be uploaded to Virtuozzo Hybrid Infrastructure and specified during VM creation. It will be injected into the VM by cloud-init and used for OpenSSH authentication. Keys injection is supported for both Linux and Windows virtual machines.

**Note**

You can specify an SSH key only if you deploy a VM from a template or boot volume (not an ISO image).

Before using the SSH keys feature, make sure the following requirements are met:

- The cloud-init utility is installed in a VM template or boot volume.
- OpenSSH Server is installed in a Windows template or boot volume.

For the instructions on preparing templates or boot volumes, refer to "Preparing templates" (p. 33).

To add a public key, do the following:
1. Generate an SSH key pair on a client by using the ssh-keygen utility:

```
# ssh-keygen -t rsa
```

2. On the SSH keys screen, click Add key.

3. In the Add SSH key window, specify a key name and copy the key value from the generated public key located in `/root/.ssh/id_rsa.pub`. Optionally, you can add a key description.

---

**Note**

If a key has been injected into one or more VMs, it will remain inside those VMs even if you delete it from the panel.
